

# L02: Logistic Regression

## Classification with Probability Estimates

Methods and Algorithms

Spring 2026

- 1 Problem
- 2 Method
- 3 Solution
- 4 Practice
- 5 Decision Framework
- 6 Summary

**By the end of this lecture, you will be able to:**

1. Derive the MLE for logistic regression via gradient of the log-likelihood
2. Analyze model fit using deviance, LRT, AIC/BIC, and Hosmer-Lemeshow
3. Evaluate classification performance using ROC, calibration, and cost-sensitive metrics
4. Apply logistic regression to credit scoring with regulatory interpretation (Basel PD)

**Finance Application:** Credit scoring and probability of default (PD)

---

**Bloom's Levels 4–5: Analyze, Evaluate, Create**

# Why Logistic Regression?

## The Business Problem

- Banks must decide: approve or reject loan applications
- Need probability of default, not just yes/no prediction
- Regulatory requirement: interpretable, auditable models

## Why Not Linear Regression?

- Linear regression can predict values outside  $[0,1]$
- Binary outcomes need probability-based approach
- Logistic regression outputs calibrated probabilities

---

Logistic regression: the industry standard for credit scoring since 1980s

# The Sigmoid Function

## From Linear to Probability

Logistic function (probability of class 1):

$$p(y = 1|x) = \frac{1}{1 + e^{-(\beta_0 + \beta^T x)}} \quad (1)$$

Maps any real number to (0, 1); smooth, differentiable, invertible

Log-odds (logit):

$$\log \frac{p}{1-p} = \beta_0 + \beta_1 x_1 + \cdots + \beta_p x_p \quad (2)$$

**Decision boundary:**  $P(y = 1|x) = 0.5 \iff \mathbf{w}'\mathbf{x} + b = 0$

The boundary is a hyperplane; points on one side predict class 1, the other class 0

## Maximum Likelihood Estimation:

$$\ell(\beta) = \sum_{i=1}^N [y_i \log p_i + (1 - y_i) \log(1 - p_i)] \quad (3)$$

where  $p_i = p(y_i = 1 | \mathbf{x}_i)$ .

Maximize log-likelihood = minimize cross-entropy loss (convex, guaranteed global optimum)

AUC = probability random positive ranks higher than random negative

# Precision-Recall Trade-off

Use PR curve when classes are imbalanced (common in fraud detection)

# Confusion Matrix: Reading the Results

Confusion Matrix: Credit Default Prediction

Accuracy: 92.0%  
Precision: 58.3%  
Recall: 70.0%  
F1 Score: 0.64

[https://github.com/Digital-AI-Finance/methods-algorithms/tree/master/slides/L02\\_Logistic\\_Regression/06\\_confusion\\_matrix](https://github.com/Digital-AI-Finance/methods-algorithms/tree/master/slides/L02_Logistic_Regression/06_confusion_matrix)

FP = approve bad loans (costly), FN = reject good customers (lost revenue)

## Open the Colab Notebook

- Exercise 1: Implement logistic regression from scratch
- Exercise 2: Train model on credit scoring data
- Exercise 3: Evaluate with ROC curve and confusion matrix
